Advisory Circular

Subject: Change 2 to AIRPORT WINTER SAFETY
AND OPERATIONS

Date: 3/27/95
Initiated by: AAS-100

AC No: 150/5200-30A
Change: 2

1. PURPOSE. Chapter 2, Winter Operations on Airports, has been revised to incorporate additional guidance in conducting runway friction surveys under winter operational conditions, and to provide a generic specification for fluid based runway deicers/anti-icers that may be used on aircraft operational areas.

The change number and date of change is shown at the top of each page. The changed material is indicated by lines in the left-hand column margins.

PAGE CONTROL CHART

LEONARD E. MUDD
Director, Office of Airport Safety and Standards

CHAPTER 2. WINTER OPERATIONS ON AIRPORTS

7. SAFETY REQUIREMENTS. Snow, ice, and slush should be removed as expeditiously as possible to maintain runways, high-speed turnoffs, and taxiways in a "no worse than wet" condition. Surface friction can be improved by application of abrasive material when unusual conditions prevent prompt and complete removal of slush, snow, or ice. Operations of snow removal equipment and support vehicles must be conducted to prevent interference and conflict with aircraft operations. This responsibility is shared by both airport personnel and aircraft operators. The reduced hours of daylight during the winter and frequent low visibility conditions, resulting from fog, blowing snow, or precipitation, require extra care during field operations and greater attention to enhancing visibility of equipment performing winter maintenance (i.e., snow removal, friction enhancement, etc.).

a. Airport Operator. Airport operators have a major duty to ensure the safety of operations at their facilities. This involves performance according to accepted principles, ensuring a high standard of care, and providing state-of-the-art standards in equipment and techniques. Care should be taken that the snow and ice removal plan in the airport's certification manual is current, complete, and customized to the local conditions. All airport leases and agreements should be clear and specific and cover the duties and responsibilities of lessees to carry out their snow and ice control duties. Airport operators, however, have the duty to warn of any change in published procedure or change in the physical facility. As an example, an operator should give timely or proper notice of pavement or visual aids which may have been damaged by a snow plow. Complete documentation of compliance with the certification manual should be kept.

b. Snow and Ice Control Contractors. The principles of ensuring safety of operations also apply to contractors. In particular, agreements should be clear and specific regarding duties, procedures for snow and ice control, responsibilities for communications and control, and contingencies. Contractors should be given a copy of the airport certification manual as well as the snow plan.

c. Airman's Information Manual (AIM). The procedures for pilot braking action reporting and runway friction reporting are given in the AIM. These procedures cover how pilots report aircraft braking action to ATC and how ATC reports friction numbers obtained from airport management to pilots during winter operations.

8. ISSUES. Snow, ice, and slush on aircraft movement surfaces can degrade the coefficient of

friction and reduce aircraft braking and directional control.

a. Runway Operations. Snow, ice, slush, and standing water impede aircraft acceleration. Although acceptable limits vary by aircraft, most jet aircraft flight manuals limit the aircraft to landing with 1 inch or less of slush or standing water on the runway and to taking off with one-half inch or less of slush or standing water on the runway. AC 91-6A, Water, Slush, and Snow on the Runway, provides additional information concerning the operation of turbojet aircraft when water, slush, and snow are on the runway.

b. General Aircraft Surface Operations. Other winter safety concerns include:

(1) Obscured Visual Aids. In-pavement and edge lights, taxiway lights, runway markings, airport guidance signs, and visual approach slope indicators need to be maintained free of snow and ice.

(2) Obstructions. Hazardous snow banks, drifts, windrows, and ice ridges, which could come into contact with any of the aircraft wing or nacelle surfaces, should be prevented or eliminated.

(3) Navigational Aids. Any snow or ice which affects the signal of electronic navigation aids must be removed.

c. Parking Ramp Operations. Snow, ice, and slush accumulations on ramps and parking or holding areas create safety hazards. Three effects of such accumulations are:

(1) Slick Surfaces. Equipment and personnel operating on a slick or icy pavement surface may not have sufficient traction to start, stop, or even remain in place when encountering exhaust blast from other aircraft. Maintaining directional control under these conditions is also a very real problem.

(2) Power Runup. Pilots of parked or holding aircraft (especially turbojet aircraft) must apply increased power to break away, maneuver, and taxi under adverse surface conditions. The resultant blast may damage other aircraft or ramp support equipment and could even injure ramp personnel.

(3) Obscured Visual Aids. The absence of visible painted markings or obliterated sign messages could make maneuvering on ramp areas difficult. Pilots, unable to see these visual aids, are hard pressed to judge direction and obstacle clearances.

9. Control.

a. Pre-season Planning Meetings. Prior to each winter season, a planning meeting, or series of meetings, should be held to prepare for winter operations. These planning meetings offer an opportunity to collectively assess the previous year's program and the impact of planned aircraft ground de-icing/anti-icing activities on that program. The makeup and subjects normally covered at these meetings include:

(1) Airport Snow and Ice Control. These program meetings are normally facilitated by the chairman of the snow committee, usually the airport manager or his/her designee. Membership should include representatives of the airport's operations and security staffs, the airlines, pilots, air traffic control staff, fixed base operators, and military. Holding a series of meetings will allow separating issues into two groups: those of concern to only the airport operator, and those also of interest to airport tenants. Typical subjects to be reviewed and addressed are:

(a) the snow removal plan, identifying any needed revision;

(b) security procedures, including snow season driving rules and regulations;

(c) staffing requirements;

(d) the inventory of vehicles, including spare parts/spare parts contracts;

(e) specifications for procurement of new vehicles or equipment;

(f) specifications for snow removal and material supply contractors;

(g) a snow removal haul plan, including the site(s) for snow dumps;

(h) the location of snow fences;

(i) a preventative maintenance program for snow removal vehicles;

(j) any requirements for containment/collection of chemicals;

(k) communications frequencies and procedures; and

(l) air traffic control procedures.

(2) Aircraft Deicing. The airport operator should act as a facilitator and arrange a meeting among the parties that may be affected by aircraft deicing plans, including those plans required of air carriers operating under 14 CFR Part 121. These parties include airport management and consultants, the air carriers, other airport users, corporate tenants,

pilot representatives, and FAA Air Traffic Control. The focus of these meetings is to assess the impact of any aircraft deicing activities on airport operations and to identify actions that can be taken by the various parties to maximize the efficiency of operations during icing conditions. For example, the committee may be able to identify the most effective locations for secondary deicing to be conducted and establish procedures for its implementation. At most airports one meeting prior to the start of the winter season should suffice. However, at other airports, subsequent meetings may be necessary to assess the effectiveness of plans and modify them if necessary. Typical subjects to be addressed are:

(a) assessment of all air carriers' deicing programs from the previous year, e.g.:

(i) review aircraft surface flow strategies;

(ii) review ground time and takeoff clearances after deicing; and

(iii) analysis and adjustment to aircraft deicing plans.

(b) actions needed to maximize efficiency of operations during icing conditions, e.g.:

(i) identification of locations for aircraft deicing, including remote areas;

(ii) planning taxi routes to minimize ground time;

(iii) developing rates that control deiced departures;

(iv) allocating departure slot capacities;

(v) determining de-icing crew needs; and

(vi) verifying communication procedures between air traffic control and aircraft to be deiced.

(c) any requirements for containment/collection of chemicals.

b. Evaluation Meetings. It may be helpful to conduct meetings during the season to evaluate, and if necessary, revise procedures.

c. Snow Committee. All airports subject to annual snowfall of several inches or more or icing conditions should have a snow committee. The committee size and function will vary depending on the frequency and amount of anticipated snowfall and the size of the airport. The formally constituted snow

committee expedites decision making, reduces the response time for keeping runways, taxiways, and ramp areas operational, and improves the safety evaluation process which determines when or if a runway should be closed. A committee may be composed of representatives of airport management and operations staffs, airline flight operations departments and/or fixed-base operators, the air traffic control tower (ATC), the flight service station, airway facilities (AF), the National Weather Service, other meteorological services, and any other interested or concerned parties. Airlines normally provide information on aircraft operational limitations and assist in evaluating pavement surface conditions. Snow committees are generally chaired by the airport manager or his representative. Committees have proved useful, not only in day-to-day operations (because communications are enabled), but in identifying long-range equipment needs and selecting and applying ice control chemicals. Snow committees normally critique past season's activities. Many snow committees also critique responses after each storm event.

d. Snow Control Center. Airports in frequent or heavy snowfall areas should set up a special facility for all snow and ice control activities (i.e., a "Snow Desk" or "Snow Control Center"). The snow desk or snow control center will normally inform air carriers and the ATC of expected runway opening and closing times and serve as a prime source of field condition information. The size and complexity of this facility will depend on the size of the airport, local climate conditions, and the personnel available. Communication between the ATC tower, snow and ice control equipment and/or supervisors' vehicles, and other support elements need to be provided. Status boards are often used for displaying the type, identification number, status, and location of each piece of equipment. A status board is also useful for recording the condition and inspections of airport surfaces and visual aids. The snow control center can keep an equipment checklist to supplement the status board and a visual inspection to ensure that all equipment has cleared runways prior to resumption of aircraft operations.

e. Snow Removal Plan. Every airport where snowfall is likely should have a written plan which states the procedures, equipment, and materials to be used by the airport in removing snow and ice. It should set out maintenance objectives and the priorities assigned to the airport movement areas, establish and define areas of responsibility (including who can close a runway), establish operational requirements and procedures, and define relationships with contractors if used. The plan should also address any unique environmental, climatic, and physical conditions affecting the airport. Elements that should be in this plan are pre-season preparation, snow committee composition, snow desk or snow control center location, equipment, personnel training, weather

reports, field condition reports, clearance criteria, clearance priorities, supervision, and communications. The snow plan should be flexible enough to allow snow and ice removal operations to change with changing weather and operational procedures. The snow committee at the airport can be charged with helping the airport operator keep the snow plan up to date. The sophistication or detail included in a snow plan will necessarily increase with the increasing size and complexity of the airport. A typical snow plan is included in appendix 2.

10. SNOW REMOVAL PRINCIPLES. Certain principles or objectives form the basis for a snow removal plan. These are discussed below:

a. Snow Removal. Snow impedes the passage of wheels by absorbing energy in compaction and displacement. The resulting drag increases as the water content of the snow increases. Wet snow and, in particular, slush will accumulate on all exposed surfaces subject to splashing from the landing gear, degrading flight control effectiveness or possibly preventing retraction of landing gear. Engine flameout can also be caused by wet snow. Even dry snow will accumulate on the landing gear and underside of the fuselage because of engine heat and the use of reverse thrust. A slush-covered pavement will reduce friction coefficient and can also cause hydroplaning. It is, therefore, necessary to remove snow from Priority 1 (active) runways as soon as possible after snowfall begins. Dry snow falling on a cold dry pavement will generally not adhere and may be blown off by wind or aircraft operations. Under these circumstances, only brooming may be needed to prevent compacted snow tracks from forming. Wet snow cannot be blown off the pavement and will readily compact and bond to it upon the passage of wheels.

b. Height of Snow on Shoulders. Snow plowed off the runways must be reduced in height, sufficient to provide clearance for wings, engines, and propellers [see chapter 3, paragraph 21b(6)]. Eliminating windrows at the runway edge will also reduce the formation of drifts onto the runway. These drifts, often called finger drifts, frequently take the form of long, intermittent, and possibly narrow snow projections which taper in width and height and can cause loss of aircraft directional control. Furthermore, snow cleared from the runways should not be deposited within a navigational aid (NAVAID) critical area, especially a reflecting plane area (see figures 3-6a and 3-6b).

c. Ice and Bonded Snow Prevention. Proper application of approved chemicals on the pavement prior to or during the very early stages of a snowfall will reduce the likelihood of compacted snow bonding to the pavement. Prompt treatment will also reduce the effort needed by either mechanical or chemical means of removing the snow. Additionally, chemicals should not be used where their melting abilities may cause dry

blowing snow to accumulate on pavement surfaces in the form of slush.

d. Response to Freezing Rain. Freezing rain will bond to a cold pavement surface and will require special treatment depending on the pavement surface temperature. If the pavement surface temperature is below freezing, chemical application may be the most effective control measure. On the other hand, if the pavement surface temperature is above freezing and a frozen rain (slush) develops, a more effective method of control would be brooming.

e. Effect of Chemicals on Friction.

(1) Deicing chemicals may initially degrade the frictional level of a pavement surface upon application because of the concentrated chemical film that will occur on the surface area. This is especially true with liquid chemicals. However, after a short period of time, the frictional quality of the pavement surface should recover if the microtexture of the pavement surface is sound.

(2) During anti-icing, pavements in otherwise good condition will not experience an unsafe drop in friction levels when chemicals are applied at the manufacturers' recommended rates. On the other hand, pavements with poor microtexture due to wear or contamination by rubber deposits may become slippery [Effects of Runway Anti-Icing Chemicals on Traction (DOT/FAA/CT-TN 90/53), Nov. 1990].

(3) After the threat of inclement weather has passed, prompt cleanup measures should be initiated to remove surface contaminants prior to aircraft operations.

f. Communications Equipment. Two-way radios provide the primary communication between snow and ice control elements, i.e., snow control center, supervisory vehicles, and often times with snowplows, brooms, and other equipment. All units operating on runways and taxiways should be able to communicate on the appropriate airport advisory frequency or be under the control of a radio-equipped vehicle. Methods of signaling to indicate to the operators the necessity for clearing the runway or changing the removal plan should be worked out in advance. Some airports use a flashing beacon on supervisory vehicles as a signal. This signal beacon is separate and distinct from the flashing beacon that should be operating whenever vehicles are in an aircraft movement area. High noise levels in snow and ice control equipment may justify the installation of radios equipped with headsets and noise-canceling microphones.

g. Clearance around NAVAIDs.

(1) Snow removal around FAA localizers, glide slope installations, transmissometers, etc., should

commence in conjunction with runway/taxiway/ramp snow control based upon the snow plan and the Instrument Landing System (ILS) snow depth criteria agreed to with the FAA airway facilities sector manager or designee. Prior to starting removal and after finishing removal, the air traffic control tower, flight service station, UNICOM, or appropriate facilities should be contacted. No equipment should be moved into the NAVAID areas until all aircraft approaches are completed. In addition, the local AF office should be contacted before beginning removal actions unless the glide slope has been Notices to Airmen (NOTAMED) out of service. Clearance around non-Federal NAVAIDs should be accomplished according to the facility's operations/maintenance manual.

(2) Snow fences can also minimize snow accumulation around NAVAIDs and other sensitive facilities. The nearest AF office should be contacted prior to erection of any snow fence for technical guidance and determination of the effect such structures will have on the proper functioning of the NAVAIDs. Failure to remove the snow in areas adjacent to the NAVAID may result in the restriction or shutdown of the facility. The airport sponsor should have an agreement with AF related to the conditions for which snow removal must be undertaken and the limits of the required snow removal to preclude restriction of the facility.

11. PRESEASON PREPARATIONS. Preparation for the next winter season should begin as soon as the previous winter season ends. A review of the past winter's experiences and problems should be made as soon as possible while the experience is still fresh in mind.

a. Equipment and Supplies. The condition of the airport snow control equipment should be determined, repairs scheduled, and replacement parts not in stock ordered. Ice control chemicals and abrasives should be ordered to ensure their being on hand before the first snowfall of the following winter season. Chemical and abrasive spreading equipment should be calibrated to ensure application of a known, controlled amount of material. The correct spread rate should be based on the prevailing conditions and the guidance provided in chapter 3.

b. Training and Communications. Crews should be trained in the operation of the equipment, and practice runs should be made with the equipment in typical operational scenarios. Also, the crews should be taught general maintenance and repair techniques for the vehicles and be trained in communication procedures and terminology, as well as be completely familiarized with airport layout, marking, signs, and lighting. A complete check of communication equipment should be made. Operator training on the use and repair of specific pieces of equipment is extremely important as it allows more

efficient use of the equipment and less likelihood of breakdowns during operation.

c. Installation of Snow Fences. Immediately prior to the onset of a winter season, snow fences should be installed at locations where prior observation has shown they will be effective in minimizing accumulation (see paragraphs 10g(2) and 21a(2)).

d. Identification of Disposal Areas. If there is insufficient storage space for snow near the areas to be cleared and no melting or flushing means are available, hauling to a disposal site may be necessary. In that case, a site should be selected before winter in an area where the snow pile will not interfere with aircraft operations, will be readily accessible, and will not interfere with the airports' NAVAIDs. The disposal site selection should be coordinated with the local AF Sector Office. Careful consideration must be given to drainage in selecting a land disposal site as the ground will remain snow-covered or wet long after all other snow has melted and seasonal vegetative growth will be delayed. If large quantities of snow must be handled, a tracked bulldozer may be necessary to push the snow from the truck dumping point into a pile. This will reduce the area occupied by the snow and prevent haul trucks from becoming stuck in the dumped snow. Debris remaining after the spring melt will need to be cleaned up. Disposal by use of melting devices is discussed in chapter 3.

12. AIRFIELD CONDITION ASSESSMENT.

a. Weather Reports. Appropriate response to a snow or ice removal event depends on accurate information about an approaching storm and the likely effect of precipitation on airport surfaces. The snow or ice removal task can be reduced and costs lessened by a prompt, effective response to a storm warning; in addition, unnecessary callouts and other mobilization costs can be eliminated by responding appropriately to accurate storm forecasts. In many areas, good forecasts can be obtained from the National Weather Service. Where these are very general, both with regard to geographic area and time of the precipitation event, contract weather services are also available and can provide local specific forecasts and short-time warnings. Some airports have installed color weather radar monitors on which views of precipitation cells can be called up from local or distant radars. Another option may be procurement of a weather radar system including x-band radar (designed specifically for snow and low-level precipitation conditions like "lake effect storms"). At smaller airports, a telephone network with outlying areas (possibly county or State highway offices) can be used to track approaching storms.

b. Pavement Surface Condition Sensors. Sensors embedded in the pavement to measure surface conditions serve two functions: (1) they provide a precise measure of the pavement temperature and they indicate the presence of water, ice, or other

contaminant; and (2) they transmit this information to the snow control center to provide an important part of the information necessary for selecting the most appropriate snow and ice control strategy. Many factors influence pavement temperature: surface color and composition, wind, humidity, solar radiation, traffic, and the presence of residual deicing chemicals or other contaminants. Since pavement temperature lags behind air temperature, use of air temperature to infer the condition of the pavement surface is imprecise and can be very misleading. Ice will not form unless the pavement temperature reaches the freezing point; therefore, knowledge of the direction and rate of change of pavement temperature will provide a predictive capability for the formation of ice. Sensors are particularly valuable in the timing of anti-icing applications of chemicals (see Chapter 3). If ice or compacted snow has accumulated on pavements, knowledge of the pavement temperature will guide selection of chemical and application rate to achieve clearance within a specified time with the minimum amount of material.

c. Field Condition Assessment. The snow control center must be aware of the surface conditions of all movement areas in order to plan and carry out appropriate maintenance actions. Runway condition reports received from pilot reports, "snow team" personnel, friction measurements (paragraph 13), or pavement condition sensors can be used to assess the surface state. This same information forms the basis for field condition reports. In addition to the usefulness for efficient snow and ice removal, field condition reports can enhance aircraft safety when provided to pilots during winter operations. Therefore, when the airport has appropriate equipment and trained personnel, these reports should be prepared and promulgated in accordance with procedures and formats set forth in paragraphs 13 and 14.

13. RUNWAY FRICTION SURVEYS. Under certain winter operating conditions, difficulties in stopping and/or controlling aircraft on snow or ice-covered runways raises the potential for an accident or incident. Pilot braking action reports oftentimes have been found to vary significantly, even when reporting on the same frozen contaminant surface conditions. Using a truck or automobile to estimate aircraft braking action is subjective and of questionable benefit. For this reason, airports should conduct friction surveys to obtain an indication of the existing level of friction on runways contaminated with snow and/or ice. To ensure that data collected is accurate, it is important that these surveys be conducted by qualified personnel using approved equipment. While it is not yet possible to calculate aircraft stopping distance from friction measurements, data have been shown to relate to aircraft stopping performance under certain conditions of pavement contamination, and are considered helpful by pilots' organizations. Further guidance on runway friction measurement may be found in Advisory Circular 150/5320-12, Measurement, Construction, and

Maintenance of Skid-Resistant Airport Pavement Surfaces.

a. Conditions Acceptable for Conduct of Friction Surveys on Frozen Contaminated Surfaces. The data obtained from friction surveys are generally considered to be reliable when the surface is contaminated by:

(1) ice or wet ice. ("Wet ice" is a term used to define ice surfaces that are covered with a thin film of moisture caused by melting. This film deposit is of minimal depth, insufficient to cause hydroplaning), or

(2) compacted snow (any depth).

Note: The above conditions can be expected after mechanical methods have removed all winter contaminants possible. Realistically, a small amount of dry snow, or wet snow/slush will often remain on the surface. It is generally accepted that friction surveys will be reliable as long as the depth of dry snow does not exceed 1 inch (2.5 cm), and/or the depth of wet snow/slush does not exceed 1/8 inch (3 mm).

b. Conditions Not Acceptable for Conduct of Friction Surveys on Frozen Contaminated Surfaces. The data obtained from friction surveys are not considered reliable if conducted under the following conditions:

(1) when there is more than .04 inch (1 mm) of water on the surface, or

(2) when the depths of dry snow and/or wet snow/slush exceed the limits in the note above.

c. When to Conduct Friction Surveys on Frozen Contaminated Surfaces. The airport operator should conduct friction surveys whenever it is felt that the information will be helpful in the overall snow/ice removal effort. The following guidelines, however, pertain to friction surveys conducted for the benefit of aircraft operators. Friction surveys should be conducted:

(1) when the central 60 feet (18 m) of the runway, centered longitudinally along the runway centerline, is contaminated over a distance of 500 feet (150 m) or more, subject to the limitations in paragraphs a. and b. above;

(2) whenever visual runway inspections and/or pilot braking action reports indicate that runway friction is changing;

(3) following anti-icing, de-icing, or sanding operations;

(4) at least once during each eight hour shift while contaminants are present; and

(5) immediately following any aircraft incident or accident on the runway.

d. Friction Measuring Equipment. There are two basic types of friction measuring equipment available that can be used for conducting friction surveys on runways during winter operations - Decelerometers (DEC) and Continuous Friction Measuring Equipment (CFME).

(1) Continuous Friction Measuring Equipment (CFME). CFME devices are the preferred equipment and are recommended for measuring friction characteristics of pavement surfaces covered with frozen contaminants. CFME's are likewise recommended for use at airports that have significant turbojet aircraft operations. They provide a continuous graphic record of the pavement surface friction characteristics with friction averages for each one-third zone portion of the runway length. They may be either self-contained or towed. Advisory Circular 150/5320-12, Measurement, Construction, and Maintenance of Skid-Resistant Airport Pavement Surfaces, contains performance standards for CFME in Appendix 4, and a list of approved equipment in Appendix 5.

(2) Decelerometers. Decelerometers are recommended for airports where the longer runway downtime required to complete a friction survey is acceptable. Decelerometers may be either electronic or mechanical. Neither type of decelerometer will provide a continuous graphic record of friction for the pavement surface condition. They provide only a spot check of the pavement surface. On pavements with patches of frozen contaminants, decelerometers may be used only on the contaminated areas. For this reason, a survey taken under such conditions will result in a conservative representation of runway braking conditions. This should be considered when using friction values as an input into decisions regarding runway treatments. In addition, any time a pilot may experience widely varying braking on various portions of the runway, it is essential that the patchy conditions be noted in any report intended to relay friction values to pilots. Electronic or mechanical decelerometers may serve as backup equipment at airports that have a more sophisticated primary device. Approved decelerometers are listed in Appendix 5. Performance standards for decelerometers may be found in Appendix 6

(a) Electronic Decelerometers. Electronic decelerometers eliminate potential human error by automatically computing and recording friction averages for each one-third zone of the runway. They also provide a printed record of the friction survey data.

(b) Mechanical Decelerometers. Mechanical decelerometers should be used only at airports where the cost of an electronic decelerometer

is not justified. The runway downtime required to complete a friction survey will be longer than that for an electronic decelerometer. (A rule of thumb is that mechanical decelerometers are appropriate for use on runway ends with 30 or fewer commercial turbojet aircraft arrivals per day.) Mechanical decelerometers do not provide automatic friction averages or a printed copy of data. Busier airports that currently own mechanical decelerometers should plan to replace them with electronic versions as soon as practicable.

e. Friction Measuring Procedures.

(1) Calibration. The friction measuring equipment operator has the responsibility to ensure that the equipment is correctly calibrated in accordance with its operation manual. Some devices perform an automatic electronic calibration each time the power is turned on; others require the operator to initiate the calibration procedure. In the latter case, the electronic calibration should be performed before placing the equipment in operation for the day. The equipment operator should also check all ancillary systems (such as recording devices, tow vehicles, two-way radios, etc.). Factory calibrations of the CFME should be performed as recommended by the manufacturer, or sooner if indicated by apparently erroneous data. The operator responsible for the device should perform only adjustments recommended by the manufacturer. Factory calibration should be scheduled during the spring-summer season to ensure that the equipment will be ready for the next winter's friction surveys.

(2) Advance Coordination. Runway friction surveys take time, and while the tests are being conducted, the runway may be closed to air traffic. Airport operators should work closely with air traffic control, the airlines, and/or the fixed base operators, to minimize interruption to aircraft operations. Close coordination, communication and cooperation among all parties concerned is vital if personnel safety, traffic management, and timely friction survey objectives are to be met. The airport operator should request from air traffic control an appropriate period of time to conduct a friction survey of the runway. At a high activity airport, friction surveys may have to be conducted in segments. The airport operator should request air traffic control to plan a break in arrival and departure traffic to provide time to conduct a friction survey. With such planning, the friction survey team can be in position adjacent to the runway when air traffic control gives the clearance to proceed. This cooperative effort with air traffic control will result in minimal disruptions to aircraft operations. A letter of agreement between the airport operator and air traffic control is suggested as a means to identify the procedures and responsibilities for coordination and for reporting runway surface conditions.

(3) Air Traffic Control Clearance When Conducting Friction Surveys on Open Runways. Before proceeding with the friction survey at controlled

airports, the airport operator responsible for conducting the friction survey must contact air traffic control for runway clearance according to standard procedures and remain in radio communications during the entire time it takes to complete the friction survey on an open runway. Air traffic control will provide appropriate clearances on and off the runway to permit the airport operator access to conduct the friction survey. At uncontrolled airports, airport operations personnel must be alert for aircraft and advise any air traffic on advisory frequencies before, during, and after completion of the friction survey. In this situation, coordination between the area air traffic control, the airport operator, and the airlines is particularly important to ensure that safe and efficient aircraft operations are maintained at all times.

(4) Location of Friction Surveys.

(a) Lateral Location. On runways that serve primarily narrow-body aircraft, friction surveys should be conducted approximately 10 feet (3 m) from the runway centerline. On runways that serve primarily wide-body aircraft, friction surveys should be conducted approximately 20 feet (6 m) from the runway centerline. Unless surface conditions are noticeably different on the two sides of the runway centerline, only one survey is needed and it may be conducted on either side.

(b) Direction. The friction measuring equipment should be operated in the same direction that aircraft are landing.

(c) Runway Zones. The runway length should be divided into three equal zones; the touchdown, midpoint, and rollout zones. These zones are defined according to aircraft landing direction. If possible, the entire survey should be completed in one pass. However, if air traffic control cannot schedule enough time to do a complete friction survey, then the airport operator should request air traffic control to schedule each zone separately until all three zones have been completed.

(5) Conducting Friction Surveys Using Decelerometers. A minimum of three braking tests are recommended in each zone to determine the average friction value for that zone, resulting in a minimum of nine tests for a complete runway survey. The vehicle speed for conducting the friction survey should be 20 mph (32 km/h).

Example:

The operator obtains four readings in the touchdown zone: 25, 27, 26, and 31. The average of these readings is 27.25. For reporting purposes, the number is rounded to the nearest 5, or in this case, 25.

Four readings are obtained for the midpoint zone, 26, 28, 28, and 32. The average of 28.5 is reported as 30.

After the minimum three readings (20, 30, and 31) are obtained for the rollout zone, air traffic control instructs the operator to clear the runway. It is not required that an equal number of readings be obtained for each zone, so the three readings are averaged and reported as 30.

(6) Conducting Friction Surveys Using CFME. A friction survey is recommended for the full length of runway to determine the average friction value for each zone. The survey may be conducted at any speed up to 40 mph (65 km/h) as safety considerations allow. Towed devices (trailers), however, can become unstable, and thus provide unreliable data, when operated at speeds above 20 mph (32 km/h) on contaminated pavements.

(7) Recording Friction Survey Data. The equipment operator should record all data and observations obtained from friction surveys. Data and observations recorded can be used to assess the effectiveness of runway surface treatments and snow removal operations; and may be helpful in accident or incident investigations. Table 2 is a suggested form which can be used for this purpose. The remarks column can be used to record pilot braking action reports and associated aircraft type, and other observations of any unusual conditions existing when the friction surveys were conducted. The CFME and electronic decelerometers provide the airport operator with their own records. These records may be used to augment the suggested form as appropriate.

14. PAVEMENT CONDITION REPORTING.

a. When To Report Friction Values. Friction values should be reported to interested parties:

(1) whenever compacted snow and/or ice are present on the center 60 feet (18 m) of the runway, and friction values are below 40 on any zone of the runway; and

(2) when friction values rise above 40 on all zones of any active runway previously showing a friction below 40.

Note: The U.S. scale, using whole numbers (e.g. 10, 20, 30) corresponds directly to the ICAO scale using decimal numbers (.10, .20, .30).

b. Report Contents. The friction report should identify the runway followed by the friction number for each of the three runway zones (rounded to the nearest 5), a short description of the cause of the runway friction problem, and the time of the report. It is especially important that pilots be advised of patchy

conditions that may result in different braking action on various sections of the runway. It is not necessary to report the type of friction measuring device since the friction numbers below 40 read essentially the same for all approved devices.

Example:

The friction measuring equipment operator conducts a survey on runway 14R with CFME and obtains averages for the touchdown, midpoint, and rollout sections of 23, 27, and 32 respectively. He/she notes that the surface is contaminated by compacted snow, with patches of ice. The survey is completed at 10:15 am. The report transmitted to air traffic control would be "Friction for runway 14R, 25, 25, 30, compacted snow with patchy ice at one zero one five.

c. Reporting Procedures. The procedure for transmitting friction values to air traffic control for

dissemination to pilots may vary from airport to airport. The letter of agreement between the airport operator and air traffic control should spell out the procedures and formats for each type of event - runway closure, friction survey results, runway treatment, etc. For example, certain friction equipment manufacturers offer the airport operator an optional data link system that provides direct transmission of the friction measuring equipment data to airport operators, or air traffic control, or both. Reports may also be furnished to local operators, airlines, or other users. In the absence of a control tower on the airport, the report should be supplied to the air traffic control facility that provides approach control service or to an appropriate flight service station (FSS), fixed-base operator (FBO), or other authority to broadcast on the Unicom, Common Traffic Advisory Frequency (CTAF), or Airport Advisory Service Frequency.

d. OUT-OF-SERVICE FRICTION MEASURING EQUIPMENT. During winter operations, if friction values taken on compacted snow and/or ice have been issued on a regular basis and the equipment used to obtain these values is not available, a Notice to Airmen (NOTAM) should be issued and maintained until the equipment is restored to service. Meanwhile, runway advisories may be issued using other means of observation (e.g., pilot reports).

15. NOTAMS. Airport operators are responsible for issuing NOTAMS. AC 150/5200-28, Notices to Airman (NOTAMS) for Airport Operators, provides details of format and abbreviations for use in reporting winter conditions on aircraft movement areas. See appendix 1 for examples of NOTAM snow reports.

(7) Movement areas where aircraft will operate at high speeds such as turnoffs should receive the same snow and ice control attention as runways. Areas of low speed operation such as taxiways and ramps can also be critical under some conditions. Directional control and braking action should be maintained under all conditions.

(8) Airports with joint military operations may have arresting barriers located near the end of the active runway or the beginning of the overrun area. Great care should be taken in clearing snow from the barriers. Barriers located on the runway should be deactivated and pendants removed prior to snow removal operations. Snow should be removed to the distance required for effective runout of the arresting system. Snow removal involving arresting barriers should be coordinated with the military tenant prior to the snow removal season.

(9) In heavy snow areas, it is helpful to mark edge lights by placing flexible markers adjacent to the lights. Markers should be securely fastened in place to avoid creating a foreign object damage (FOD) hazard. They should be of a high-contrast color such as international orange to enhance visibility. The height of these units should be 6 inches (14 cm) outside of the propeller arc of the most critical airplane using the airport. Although the units are primarily used to assist snow removal equipment operators in maneuvering around the lights, pilots also find them to be useful as visual taxiing aids. Time and effort in clearing snow from around the lights is minimized by plowing as close as possible to them. The remaining snow can be blown away using an airblast unit mounted on a truck or broom or by spraying with liquid deicing chemical. In some cases, edge lights may be raised. As a last resort, hand shoveling may be necessary.

(10) The face of all signs and all lights should be kept clear of snow and in good repair at all times with priority given to lights and signs associated with holdlines and ILS.

(11) Centerline and touchdown zone (TDZ) lights inset in the pavement tend to form "igloos" of ice or compacted snow surrounding them. Heat from the lamps will melt even cold dry snow which will refreeze and adhere to the pavement and then accumulate around the lights. One method of control or removal is described in paragraph 24. To prevent damage to these lights, use rubber or plastic cutting edges or shoes and casters on plow moldboards and the front of rotary plows.

(12) Striated pavement markings are useful in reducing ice buildup.

22. SNOW DISPOSAL. Some means of disposing of snow must be provided when there is insufficient space for storage adjacent to cleared areas. This will entail loading trucks and hauling to a disposal site, pushing

the snow into melting pits sited near the areas being cleared, or portable melting pits set up over catch basins. Although melting pits eliminate long hauls and may reduce truck traffic in the ramp area, an economic analysis should be made to determine the benefit of constructing and operating them. Calculation of the thermal energy required is based on the heat of fusion of ice, 144 Btu/lb (335 kJ/kg) and the specific heat of ice, 0.5 Btu/lb (2.1 kJ/kg). Submerged combustion burners have been developed and are commercially available. A typical 10 x 8 x 8 ft (3 x 2.4 x 2.4 m) deep melting pit containing two burners can melt 120 tons of snow per hour (30 kg/s) consuming 60 gal. (227 liters) of No. 2 fuel oil per burner.

23. MECHANICAL METHODS FOR CONTROLLING ICE. Ice near the freezing point is soft and may be scraped off the pavement. Cold, hard ice bonds much more tenaciously and is difficult to remove by mechanical means. Scraping is not very effective, and attempts to lift the ice from the pavement by penetration with a wedge parallel to the pavement, have only been partially successful. Cutting edges attached to plow moldboards can be operated in contact with the pavement in the attempt to remove ice. At plowing speeds above about 10 mph (16 km/hr), front-mounted plows tend to bounce and leave ice on the pavement. Slower speeds, heavier plows, or plows which can be downloaded can reduce this "porpoising" or bouncing. Application of downward force also helps to penetrate and scrape the ice. Although down pressure can be applied by hydraulic cylinders on front-mounted plows, underbody blades can apply greater pressure without reducing steering control. All blades or cutting edges or the moldboards to which they are attached should have trip mechanisms to release the blade upon striking an obstacle in order to prevent damage to the blade, truck, pavement insert, or pavement. Carbon steel cutting edges run in contact with the pavement wear rapidly and require frequent replacement. Tungsten carbide cutting edges are extremely tough and can last for thousands of miles. They are brittle, however, and can chip upon striking metal or other very hard projections. Serrated cutting edges which cut grooves in hard ice are sometimes used and will facilitate retention of chemicals and abrasives which might otherwise be blown off. Centerline or flush lights should not be plowed with metal cutting edges contacting the pavement; rubber or polymer cutting edges will help prevent damage to the lights. Slush or very soft ice can also be removed effectively by rubber cutting edges which squeegee the pavement.

24. ANTI-ICING VS. DEICING. The most difficult task in winter maintenance occurs when snow or ice bond to the pavement. Thus the primary effort should be directed at bond prevention. Though dry snow will not readily form a strong bond even under heavy and frequent wheel passes, wet snow and ice will develop such a strong bond that mechanical removal is either difficult, slow, or damaging to the pavement. Ice

removal after formation is called deicing; preventing the bond from forming is called anti-icing or bond prevention. Anti-icing, which is recommended over deicing whenever possible, is accomplished by concentrating either thermal or chemical energy at the pavement surface. Because of the high cost of installing pavement heating systems and the large amounts of energy required to maintain the surface above freezing prior to the onset of precipitation, anti-icing/deicing with approved airside chemicals is generally more economical. Chemical application is in either solid (includes pre-wetted) or liquid form. Chemicals in liquid form are most effective for uniform anti-icing treatment of pavements. All deicing/anti-icing chemicals should be applied based on pavement temperature rather than air temperature (see AC 150/5220-13A, Runway Surface Condition Sensor-Specification Guide).

a. Deicing Chemicals. Deicing chemicals should be applied on ice 1/16 inch (1.5 mm) or less in thickness. Thicker layers of ice require an extended period of time to obtain ice-free pavement. However, solar radiation from even a cloudy sky enhances melting action to such an extent that elimination of ice thickness greater than 1/16 inch (1.5 mm) are possible.

b. Anti-icing Chemicals. The recommended chemical form for anti-icing is liquid, although solid chemicals can also be effective in this application. A dry solid chemical has the disadvantages that if applied to a cold dry surface it may not adhere and therefore, may be windblown or scattered by aircraft movements. However, certain physical properties of a solid, such as its bulk density, particle shape, etc., may reduce these tendencies. Regardless, wetting a dry anti-icing chemical, either during distribution or before or after loading into the application vehicle, improves the ability to achieve uniform distribution and improved adhesion.

25. CHEMICALS. Any water-soluble substance will lower the freezing point of water and thus promote the melting of ice. Theoretically, the lower the molecular weight and the more individual particles (ions) the substance disassociates into, the more effective the product is as an ice control chemical, assuming its solubility still remains high at the freezing temperature. For the purpose of shared information, airport operators should advise the airlines before introducing a new chemical on the airside.

a. Approved Airside Chemicals. The FAA either establishes approval specifications or, upon recognition, references the specifications of professional associations such as the Society of Automotive Engineers (SAE) through Aerospace Material Specifications (AMS) and the United States military (MIL-SPEC). The approved airside chemicals for nonaircraft applications are fluid and solid products meeting a generic SAE specification or MIL specification. These specifications require vendors to provide the airport operator with a material safety data sheet (MSDS) and certification that the chemical conforms to the applicable specification. With the increased accountability placed on airport operators to manage deicing/anti-icing chemical runoff, they should request vendors to provide certain environmental data. These data consist of pollutants that the Environmental Protection Agency and the State Department of Natural Resources require of the airport operator in their discharge reporting. Typical information includes: percent product biodegradability, biochemical oxygen demand (BOD5), chemical oxygen demand (COD), pH, presence of toxic or hazardous components, if any, and remaining inert elements after application. Related to the environment, MSDSs provide measures on how to secure large product spills and a 24-hour 800 emergency phone number. While these fluid and solid specifications cover technical requirements for deicing/anti-icing compounds, they do not address the compatibility issue of combining products during operations. Airport operators should query manufacturers about the safe and proper use of concurrently applying multiple deicers/anti-icers.. The FAA-approved airside chemical specifications are as follows:

(1) **Fluid Deicer/Anti-icer.** The approved specification is SAE AMS 1435, Fluid, Generic Deicing/Anti-icing, Runways and Taxiways. Approved products include glycol base fluids and potassium acetate base fluids.

(i) **Glycol Base Fluids.** Composition of proprietary solutions meeting this specification varies with the manufacturer, though the glycol-base content is approximately 50 percent. Application rates range from 1-2 gal/1000 ft² for deicing and from 0.2-0.5 gal/1000 ft² for anti-icing. While the specification only requires a eutectic temperature of -10 F (-23 C) or less, proprietary products are available with eutectic temperatures as low as -75 F (-59 C). Ethylene glycol, (CH₂)(OH)(CH₂)(OH), has a eutectic temperature of approximately -58 F (-50 C) for an aqueous solution of 58-78 weight percent of ethylene glycol and a freezing point of approximately 8.6 F (-13 C) for the pure fluid. Propylene glycol, (CH₂)(OH)(CH)(OH)(CH₃), has a eutectic temperature of approximately -75 F (-59 C) for an aqueous solution of 60 weight percent of propylene glycol. Propylene glycol in its pure form does not have a freezing point per se, but sets to glass below -60 F (-51 C).

(ii) **Potassium Acetate Base Fluids.** Application rates range from 1-2 gal/1000 ft² for deicing and from 0.3-0.5 gal/1000 ft² for anti-icing. While the specification requires a eutectic temperature of -10 F (-23 C) or less, proprietary products are available with eutectic temperatures as low as -76 F (-60 C).

(2) **Solid Compound Deicer/Anti-icer .**

(i) **Generic Solid.** The approved specification is SAE AMS 1431A, Compound, Solid Runway and Taxiway Deicing/Anti-icing. Approved solid compounds include airside urea, calcium magnesium acetate (CMA), sodium formate, and sodium acetate. The specification requires a phase diagram relating product dilution to freeze point. The delivered product is effective within +7 F (+4 C) of the preproduction temperature value established by the manufacturer. Application rates for a specific product are based on manufacturer recommendations.

(ii) **Airside Urea (also called carbamide).** The approved specifications are SAE AMS 1431A, Compound, Solid Runway and Taxiway Deicing/Anti-icing and MIL SPEC DOD-U-10866D, Urea-Technical. Agricultural grade urea that meets any of these specifications, termed airside urea, is acceptable. Production of this nontoxic solid white chemical, chemical formula (NH₂)₂CO, is in either powder or "shotted" ("prilled") form. The latter form's shape is small spheres of about 1/16 inch (1.5 mm) diameter. Both forms are primarily for deicing where powdered urea is frequently mixed with sand. Hot mixtures of powder or "shotted" urea and sand serve two purposes: (1) immediate increase in braking action and; (2) retention of chemical over the pavement area until it initially dissolves some of the ice and then melts the remainder. The urea deicing function is practical only at temperatures above approximately 15 F (-10 C) because of the decreasing

Application Rate of Airside Urea (lb/ft²) [kg/m²]

Ice Thickness inch (cm)	Temperature Deg. F (C)		
	30 (-1.1)	25 (-3.9)	20 (-6.7)
less than 1/32 (.08)	.016 (.078)	.023 (0.11)	.06 (0.29)
1/32 (.08) up to but not including 1/8 (.32)	.03 (0.15)	.06 (0.29)	.125 (0.61)
1/8 - 1/4 (.32-.64)	.125 (0.61)	.175 (0.86)	.275 (1.34)

melting rates below this temperature value. The decreasing melting rate is a result of urea's eutectic temperature, defined in paragraph 2(f), which is approximately 11.3 F (-11.5 C). However, the presence of solar radiation assists urea in the melting action. Pavement surface temperature and ice thickness determine the urea application rate.

b. **Landside Chemicals**. The most effective landside chemicals used for deicing/anti-icing based on both cost and freezing point depression are from the chloride family, e.g., sodium chloride (rock salt), calcium chloride, and lithium chloride. Unfortunately, these chemicals are known to be corrosive to aircraft and therefore are prohibited from use on aircraft operational areas. Although classified as salts, CMA, sodium formate, and potassium acetate are approved for airside use because they comply with an SAE specification. When any corrosive chemical is used, precautions should be taken to ensure that vehicles do not track these products onto the aircraft operational areas.

26. ENVIRONMENTAL ASPECTS OF DEICING CHEMICALS. All freezing point depressants may cause scaling of portland cement concrete (PCC) by physical action related to the chemical concentration gradient in the pavement. Deleterious effects on PCC can be reduced by ensuring sufficient cover over reinforcing steel (minimum of 2 inches (5 cm)), using air-entraining additives, and avoiding applications of chemicals for a year after placement. Concrete meeting the compressive strength outlined in ASTM C 672, Scale Resistance of Concrete Surfaces Exposed to Deicing Chemicals, will perform well when subjected to chemical deicers. No surface degradation of asphalt concrete has been observed due to approved chemicals. Deicing/anti-icing chemicals commonly used on airfields, e.g., airside urea, CMA, sodium formate, glycols, and potassium acetate, rapidly biodegrade in the environment although biological oxygen demand for some products may be high under certain cases. Low temperatures and dilution from heavy runoff during periods of use tend to minimize this. Urea decomposes to ammonia which may be quickly dissipated.

27. RUNWAY FRICTION IMPROVEMENT. Since snow and ice degrade the coefficient of friction between rubber tires and pavement and could pose an unsafe condition for aircraft, it is important to clear to bare pavement whenever possible. There are situations where complete removal is difficult or impossible to achieve within a required span of time; at temperatures approaching the eutectic temperature

of a deicing chemical, for instance, it may require an hour or more for the chemical to go into solution and melt the ice. There are two techniques for modifying the frictional coefficient of a pavement covered with ice or compacted snow, one by building in a texture on the surface and the other by surface treatment of the ice or snow. It should be emphasized, however, that an abrasive is not a deicing chemical and will not remove ice or compacted snow--in fact, heavy applications of abrasives can insulate the ice and prolong its presence.

a. **Pavement Surface Modification**. Surface texture and surface treatment modifications by themselves will not increase the coefficient of friction of ice formed on the surface but both will enhance the response of chemical treatment.

(1) **Pavement Grooving**. Grooves cut into the pavement will trap deicing chemical, reduce loss, and prolong its action. Grooves also assist in draining melt water and avoiding its refreezing. There is empirical evidence that grooves and porous friction courses modify the thermal characteristics of a pavement surface, probably by reducing the radiant heat loss, and delay the formation of ice. There do not appear to be any negative effects from grooved pavements.

(2) **Porous Friction Course (PFC)**. PFC has generally the same benefits as grooving. Open graded asphalt concrete is less effective in improving coefficient of friction under icing conditions because the open spaces will fill with compacted snow, and to a lesser extent with ice in the case of freezing rain. Most maintenance personnel have found that chemical treatment rates may need to be increased on this type of pavement compared to dense graded asphalt concrete because of drainage of the chemical. The drainage characteristics also change as abrasives accumulate in the voids and plug them.

b. **Surface Treatment**. This is the approach taken to rapidly increase the frictional coefficient of an ice surface. Two methods are available: application of coarse granular material ("abrasives") and scarifying the ice surface with a serrated blade. A friction value measured below 27 (MU equivalent), as discussed in paragraph 13, indicates that surface treatment should be initiated.

(1) **Abrasives**. Granular material provides a roughened surface on ice and thereby improves aircraft directional control and braking performance. Use of abrasives should be controlled carefully on

g. The glide slope snow clearance area for the "capture-effect" antenna configuration should be evaluated by the crew chief and cleared as shown on figure A2-3. Contact should be made with the airway facilities manager or his designee at 887-6532 and the air traffic control tower at 887-8765 before moving equipment into the ground plane area.

4. **Ice Control.** Icing conditions occur most frequently at air temperatures between 28 and 34 F (-2 and 1 C), though there have been instances as low as 5 F (-15 C) and as high as 40 F (4.4 C). Frequent contact should be made by operations staff with the National Weather Service or the contract weather service when the air temperature falls in the most probable icing range. Runway sensors which are monitored by operations division employees are important tools in determining when icing conditions may occur.

a. **Runways, Taxiways and Ramps .**

It is the policy of this airport to apply X-7V liquid deicing chemical meeting SAE specification AMS 1435 to all priority 1 movement areas as soon as the pavement surfaces become wet and the temperature is close to 32 F (0 C) as an anti-icing treatment. In the event that ice forms on movement areas, the standard procedure will be to apply prilled (solid) urea at the rate of 0.1 lb/ft² (.49 kg/m²) when the temperature is above 20 F (-6.7 C) and sand wetted with X-7V

at temperatures below this. Absolutely no chloride salts or other corrosive chemicals are to be used on aircraft movement areas.

b. **Access Roads and Parking**

Areas. Sodium chloride and calcium chloride are permissible on automobile roadways. Sand used in these areas may be treated with these chemicals to assist in adhering to the ice and to prevent stockpiles from freezing. Bridges must receive special attention since icing frequently occurs on those surfaces prior to the adjoining pavement because of cooling from underneath.

5. **Cleanup.** All snow windrows must be removed as soon as possible after a storm ends. Sand will be removed from runways as soon as the surface is dry and braking action has been restored. The crew chief and/or operations staff will ensure that this is done. The airfield should be checked for broken or damaged lights and signs and repairs should be made.

NOTE: It is useful to append lists of personnel with their phone numbers, maps showing routing of equipment teams, radio frequencies or channels assigned to snow and ice control equipment, and other special local conditions affecting operations.

Priority Areas for Snow Control at Muncho Airport

APPENDIX 4 - FAA-APPROVED DECELEROMETERS

BOWMONK SALES 589 Middlefield Road UNIT #4 Scarborough, Ontario CANADA M1V 4Y6	BOWMONK DECELEROMETER (416) 609-0858 FAX (416) 609-0827
TAPLEY SALES (CANADA) 100 Palmer Circle R.R. No. 2 Bolton, Ontario CANADA L7E 5R8	TAPLEY DECELEROMETER (905) 880-0858 FAX (416) 231-9121

APPENDIX 5 - PERFORMANCE STANDARDS FOR DECELEROMETERS

1. Scope. This appendix describes the procedures for establishing the reliability, performance, and consistency of decelerometers.

2. Certification (General). The manufacturer will certify that the electronic or mechanical decelerometers:

a. Are portable, rugged, and reliable.

b. Are capable of being fitted to vehicles qualified by the requirements given in this specification. Minimal vehicle modifications will be necessary to accommodate the mounting plates and electrical connections. Vehicles are qualified according to their size, braking and suspension system, shock absorber capabilities, and tire performance. The vehicle shall:

(1) Be either large sedans, station wagons, intermediate or full size automobiles, or utility and passenger-cargo trucks. Vehicles can be powered by either front-wheel, rear-wheel, or four-wheel drive.

(2) Be equipped with either standard disc and/or drum brakes as long as they are maintained according to the manufacturer's performance requirements. They can also qualify if they have a single sensor ABS (anti-lock braking system) installed on the rear axle.]

Decelerometers should not be installed on vehicles that are equipped with full ABS because the ABS tends to distort the sensitivity of the decelerometer resulting in friction readings that are lower than actually exist. This could result in the premature closing of runways.

A full ABS has three sensors, one on each front wheel and one on the rear axle. Decelerometers can be installed on these vehicles only if the manufacturer of the ABS approves disengagement of the sensors on the front wheels. If this modification can be satisfactorily achieved, the vehicle's brake system then becomes a single sensor ABS installed on the rear axle, which will then qualify the vehicle for conducting friction tests with decelerometers.

(3) Be equipped with heavy-duty suspension and shock absorbers to minimize the rocking or pitching motion during the application of brakes. The weight should be distributed equally to the front and rear axle of the vehicle. Ballast can be added to achieve and maintain this distribution.

(4) Have tires made from the same construction, composition, and tread configuration. Inflation pressure shall be maintained according to the vehicle manufacturer's specifications. When tread

wear is excessive on any one tire on the vehicle and/or exceeds 75 percent of the original tread, all four tires on the vehicle shall be replaced with new tires.

c. Shall be capable of measuring the deceleration of the vehicle from speeds greater than or equal to 15 mph (24 km/h) to an accuracy of 0.02 g.

d. Shall be capable of providing deceleration values upon request of the operator.

e. Shall be capable of consistently repeating friction averages throughout the friction range on all types of compacted snow and/or ice-covered runway pavement surfaces.

f. Shall not be affected by changes in vehicle velocity.

g. Shall not be affected by change in personnel or their performance in brake-applied decelerations.

h. Shall be capable of providing the vehicle operator with a readily visible deceleration reading.

3. Certification (Electronic Only). The manufacturer shall certify that the electronic decelerometer:

a. Shall be capable of providing the deceleration values in recorded order enabling the average friction value for any length of runway to be either electronically or manually calculated.

b. Shall be capable of providing average deceleration values for touchdown, midpoint, and rollout zones of the runway and the average friction value for the entire runway tested. These averages shall be automatically calculated by the decelerometers, thus eliminating potential human error when calculated manually.

c. Shall be capable of storing a minimum of 21 deceleration values via the internal microprocessor memory.

d. Shall be capable of providing a hard copy printout of stored deceleration values at the end of the testing period. The printout will record a minimum of:

(1) Providing the date.

(2) Providing the time.

(3) Providing the runway designation or heading.

e. Shall be capable of providing further information, which may be recorded at the

manufacturers discretion, e.g., make of decelerometer, ambient/pavement temperature, airport name and location, and operator identification.

4. Decelerometer Calibration. The decelerometer shall be calibrated by the manufacturer before shipping to the airport authority. The manufacturer shall provide the airport authority with a certificate of calibration, including test results of the calibration. The manufacturer shall provide a 1 year warranty for the decelerometer.

The manufacturer shall provide the airport authority with a recommended frequency for factory calibration of the decelerometer.

5. Training. The manufacturer shall provide the airport authority with training manuals and/or videos of all relevant data concerning friction measuring recording and reporting, including:

- a. An outline of the principles involved in the operation of the decelerometer-type friction measuring device.
- b. Copies of pertinent advisory circulars.
- c. Procedures for reporting results of the friction tests in NOTAM format.
